# Introduction

ChatProgram is a simple client/server application. Users can send and receive messages to each other through a Terminal interface. TCP is the protocol used to handle the connections in the application.

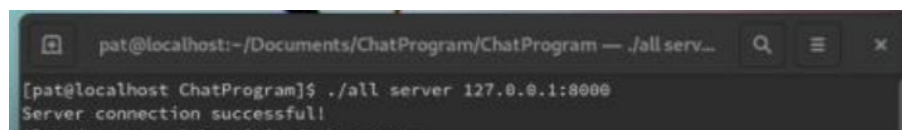

The purpose of the server is to handle connected sockets. The server maintains a list of connected sockets, receives incoming messages and sends these messages according to the list. The client establishes a connection to the server, sends messages to the server, and reads continuously for responses from the server.

Select() and system calls are used in both the client and server side. On the server side, both types of calls are used to service and multiplex incoming messages. On the client side, these calls are used to prompt the user for input and handling the “save conversation” command in a non-blocking manner.

# Instructions

## Server

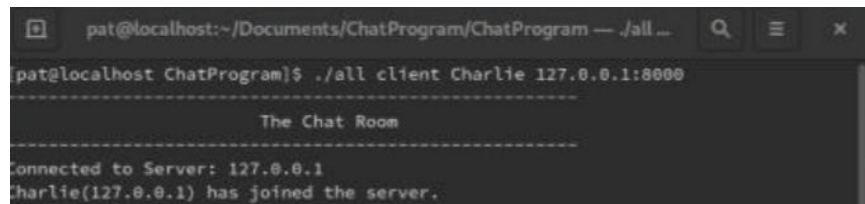

1. Go to the directory that contains the source files.
2. Open the Terminal in the directory
3. The usage pattern to run the server is as follows:  
*/all server <ip\_address>:<port>*
4. The example below runs the server at host 127.0.0.1, port 8000. The server can now listen for incoming connections.
5. The server can support up to 8 client connections.

A screenshot of a terminal window. The title bar shows 'pat@localhost: ~/Documents/ChatProgram/ChatProgram' and a search icon. The terminal content shows the command '[pat@localhost ChatProgram]\$ ./all server 127.0.0.1:8000' and the output 'Server connection successful!'.

```
pat@localhost:~/Documents/ChatProgram/ChatProgram — ./all serv...
[pat@localhost ChatProgram]$ ./all server 127.0.0.1:8000
Server connection successful!
```

## Client

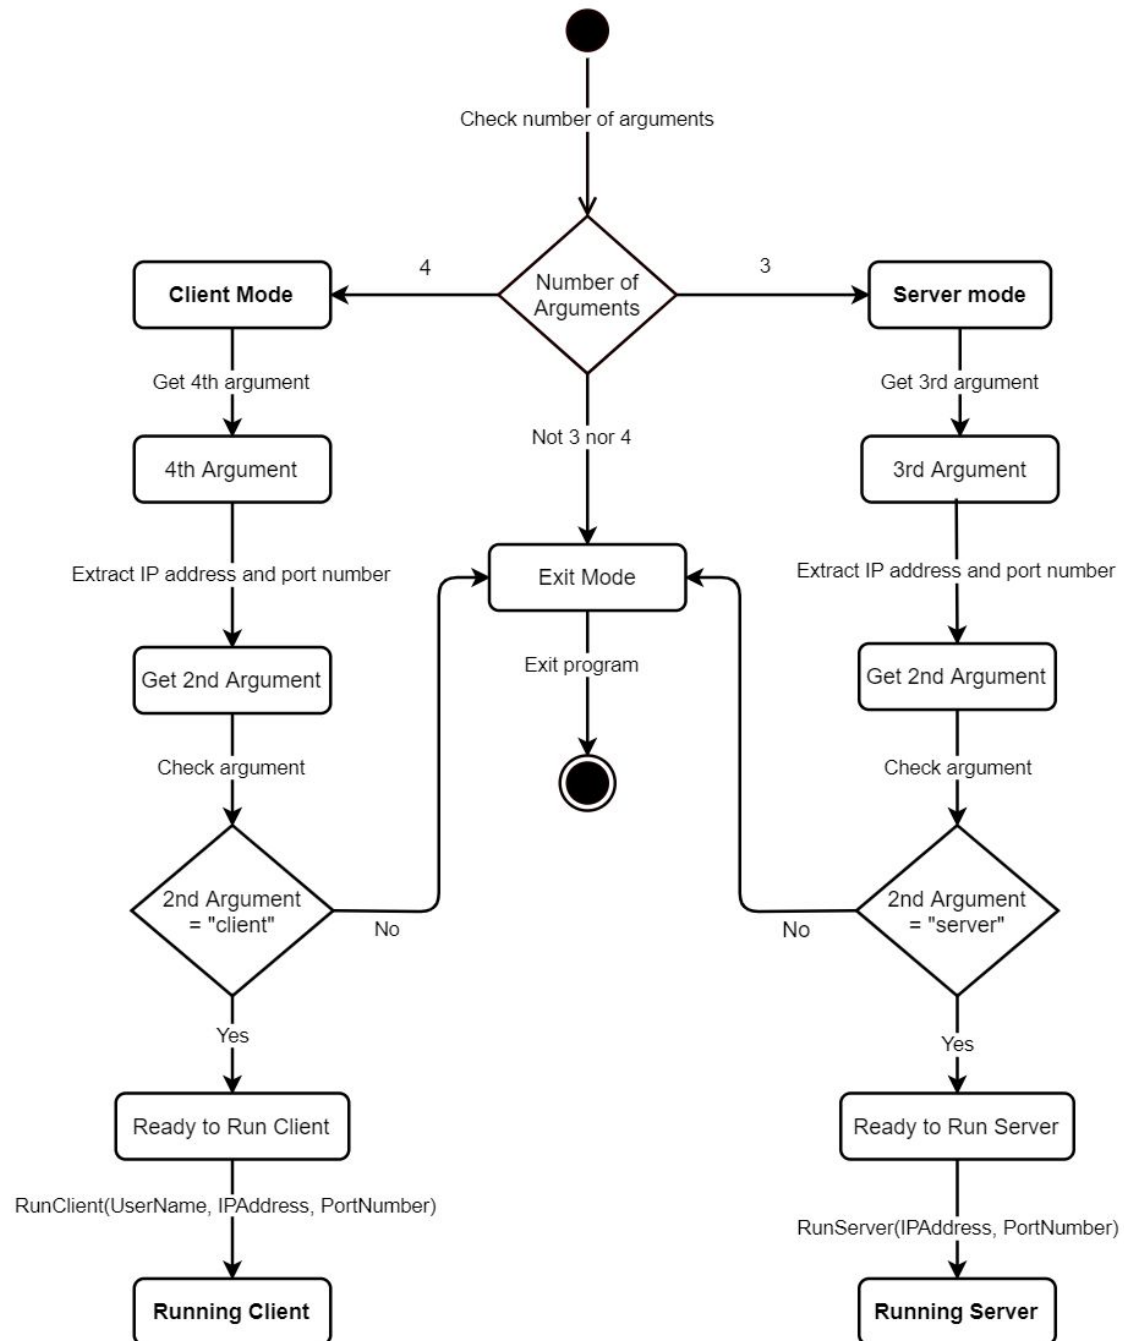

1. Go to the directory that contains the source files.
2. Open the Terminal in the directory
3. Make sure that the server is running.
4. The usage pattern to run the server is as follows:  
*/all client <username> <ip\_address>:<port>*
5. The example below runs the client at host 127.0.0.1, port 8000. The username of the client is Charlie. Charlie now can send messages to the server.

A terminal window with a dark background. The title bar shows 'pat@localhost:~/Documents/ChatProgram/ChatProgram' and some window controls. The terminal text shows a command being executed and its output.

```
pat@localhost:~/Documents/ChatProgram/ChatProgram — ./all ...  
pat@localhost ChatProgram]$ ./all client Charlie 127.0.0.1:8000  
-----  
The Chat Room  
-----  
Connected to Server: 127.0.0.1  
Charlie(127.0.0.1) has joined the server.
```

# State Diagram

## Application

## Application State Overview

Note that the first argument is the name of the executable.

### **Client Mode**

In this state, the program will check if the IP address and the port number are valid before running the client. The third argument will be used as the username/alias of the client, and the argument does not require validation.

### **Server mode**

In this state, the program will check if the IP address and the port number are valid before running the server.

### **4th Argument (Client Mode side)**

The 4th argument is a string that contains the IP address and the port number delimited by a colon (:) character. For example, “127.0.0.1:8000” is a valid 4th argument. The program will extract the IP address and port number from the string.

### **2nd Argument (Client Mode side)**

The program checks if the argument is “client.” If this is true, then the client is ready to behave as a client process. Otherwise, the program exits.

### **Ready to Run Client**

The program is ready to run as a client. The username, IP address and port number are supplied to run this process.

### **3rd Argument (Server side)**

The 3rd argument is a string that contains the IP address and the port number delimited by a colon (:) character. For example, “127.0.0.1:8000” is a valid 4th argument. The program will extract the IP address and port number from the string.

### **2nd Argument (Server side)**

The program checks if the argument is “server.” If this is true, then the client is ready to behave as a server process. Otherwise, the program exits.

### **Ready to Run Server**

The program is ready to run as a client. The IP address and port number are supplied to run this process.

**Running Client**

Given a valid IP address, a valid port number, and a username, the program will run as a client.

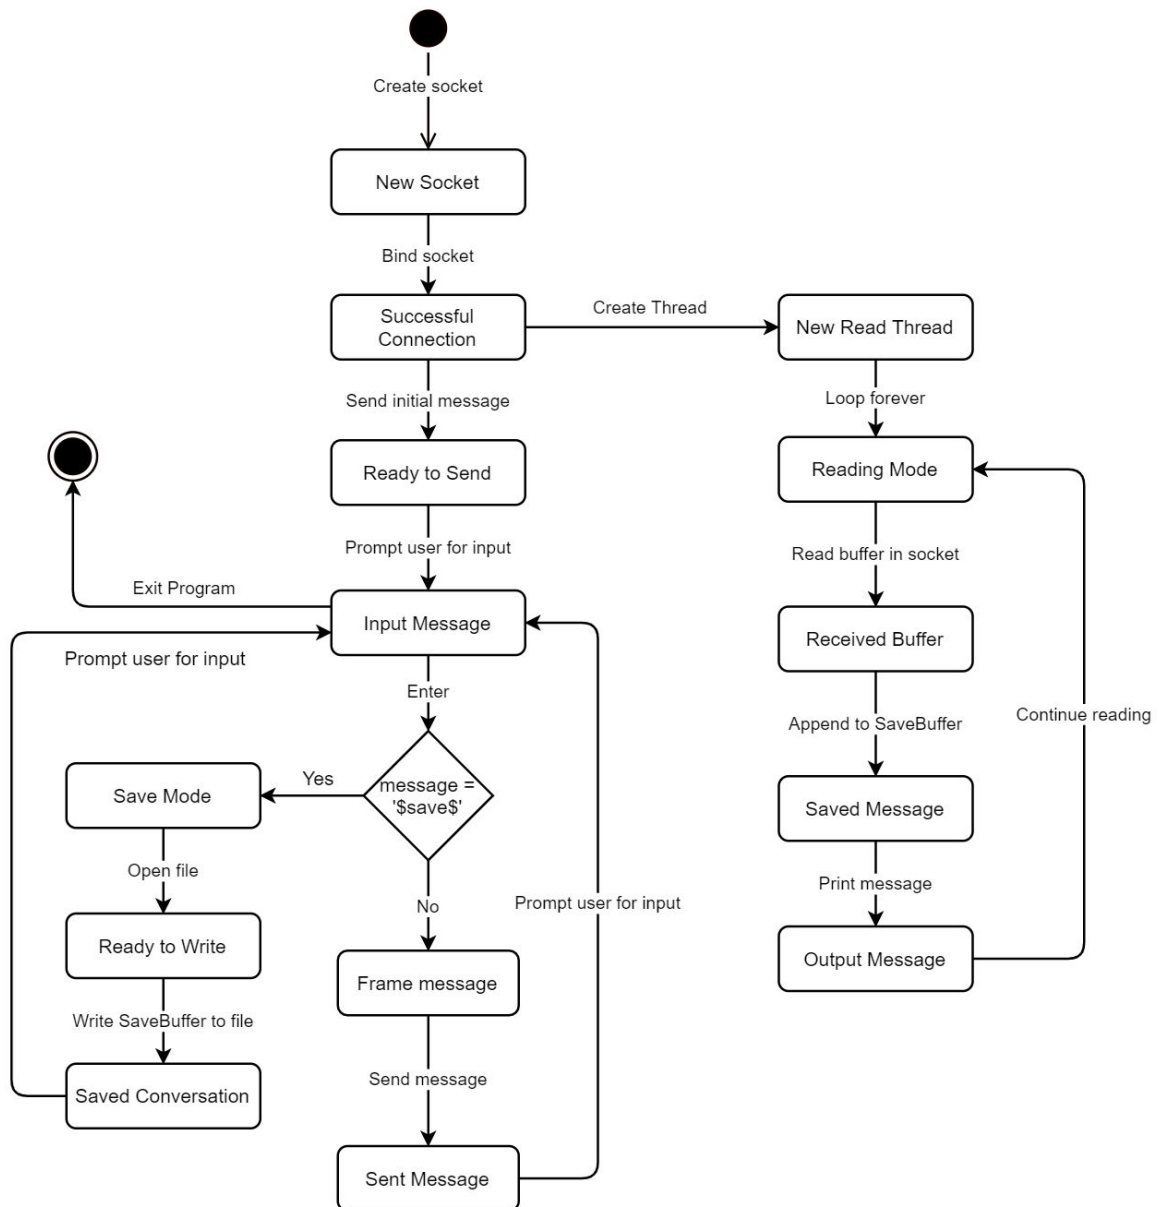

**Running Server**

Given a valid IP address, and a valid port number, the program will run as a server.

**Exit Mode**

If there is an error when verifying the context of the application, then the program terminates.

# Running Client

## Running Client State Overview

### **New Socket**

The client creates the socket descriptor.

### **Successful Connection**

In this state, the socket is bound to the IP address and port via TCP. The socket can read/write incoming data.

### **New Read Thread**

A new thread is created to read continuously for data in the socket.

### **Reading Mode**

The client reads continuously for data in the socket.

### **Received Buffer**

The client in this state has the contents of the buffer from the socket.

### **Saved Message**

The SaveBuffer contains all incoming messages. Whenever a message is read from the socket, the client will append the message to the SaveBuffer.

### **Output Message**

The incoming message is displayed to the Terminal, so that the user can see what other clients are talking about.

### **Ready to Send**

After the client sends an initial message to the server, then the client is ready to send additional messages to the server to engage with the conversation.

### **Input Message**

The client is prompted to send a message.

### **Save Mode**

When the client enters a message, then the program will check if the message is \$save\$. If this is true, then the program will enter a save mode. In this mode, the program will open a file and write the contents of SaveBuffer to the file. The file name will be called *chatlog.txt*.

**Ready to Write**

Once the chatlog.txt file is opened, then the program will write the contents of SaveBuffer to the file.

**Saved Conversation**

The file, chatlog.txt, contains the contents of the saved conversation developed by the read thread. The program will prompt the user to enter the next message.

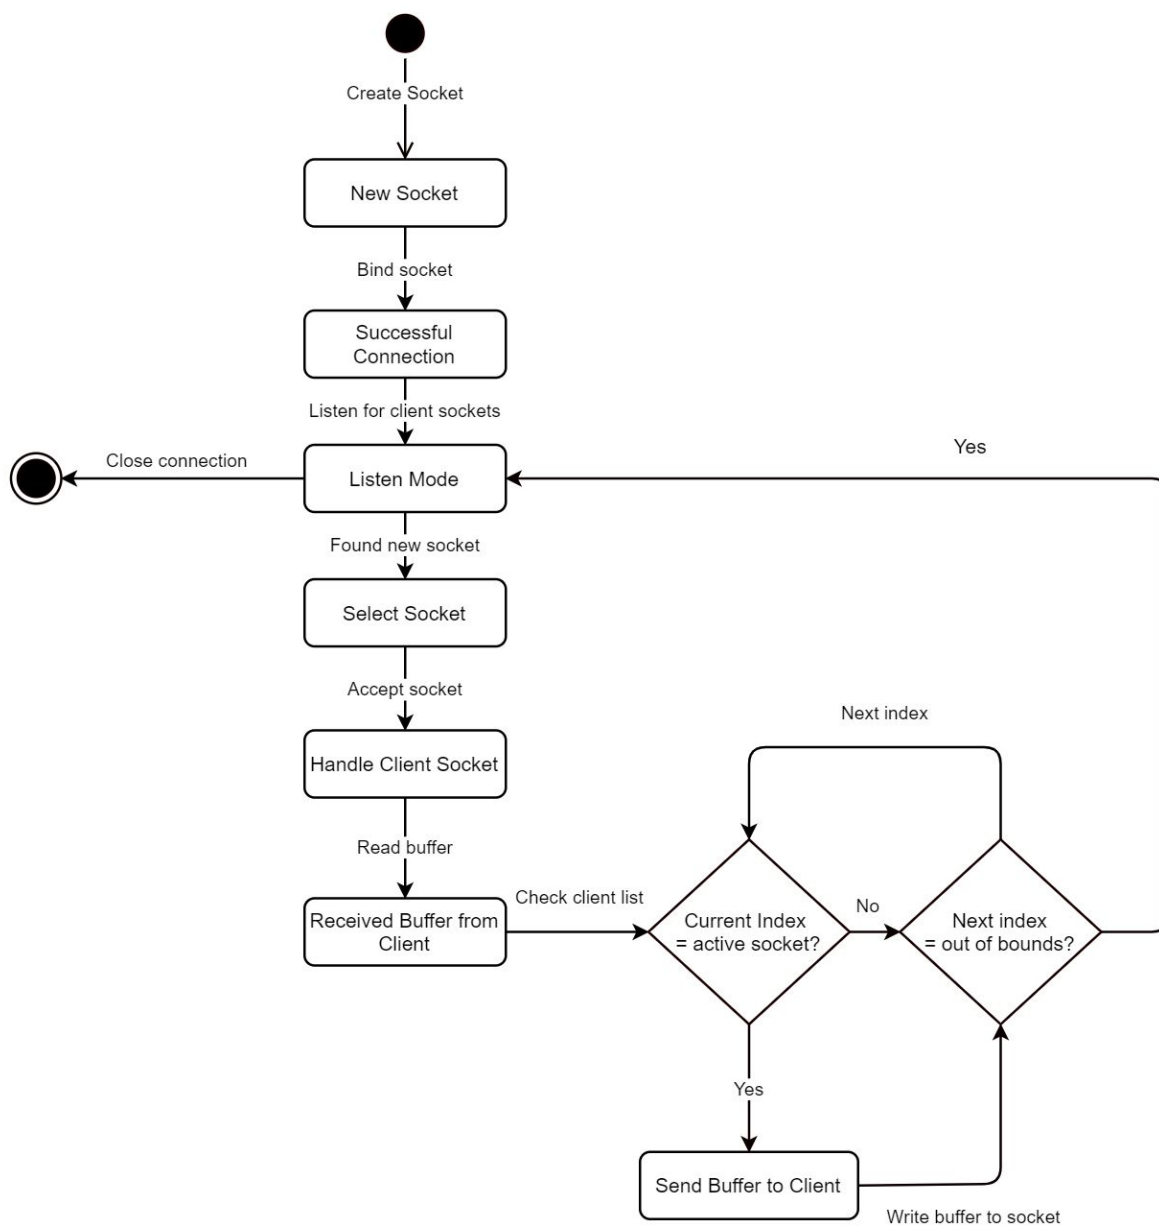

**Frame Message**

The program will decorate the message to include the username of the client.

**Sent Message**

The client will send the framed message to the server.

## Running Server

## Running Server State Overview

### **New Socket**

The server creates the socket descriptor.

### **Successful connection**

In this state, the socket is bound to the ip address and port via TCP. The socket can listen for incoming connections.

### **Listen mode**

The server will listen for incoming client connections.

### **Select socket**

Using the multiplex I/O model, the server keeps a list of client sockets. If a client socket has data in the buffer, then the server is notified and will service that particular client.

### **Handle Client Socket**

The server will attempt to read and consume the buffer from the selected client socket.

### **Received Buffer from client**

Once the server receives the buffer from the client, then the server will send the same message to each connected client. To establish that, the server will iterate the list, checking if the slot is an active connection. If the slot is an active connection, then the server will send the message to that client. Once the server runs through the list of clients, then the server will listen for the next incoming active socket connection.

# Pseudocode

## Application

### Main

```
If argument count is 3
    Tokenize third argument
    Assign IP Address to first token
    Assign Port number to second token
    Get second argument
    If second argument is not "server"
        Print error message to Terminal
        Exit program
    RunServer(IP Address, Port Number)

Else if argument count is 4
    Assign Username to third argument
    Tokenize fourth argument
    Assign IP Address to first token
    Assign Port number to second token
    Get second argument
    If second argument is not "client"
        Print error message to Terminal
        Exit program
    RunClient(Username, IP Address, Port Number)

Else
    Print error message to Terminal
    Exit program
```

## Running Client

### Client

```

Create new socket
Fill socket structure with IP address and Port number
Connect to server socket
Create SaveBuffer
Run ReadThread
Create initial message
Send initial message to server socket

Loop forever
    Prompt user for message
    If message == '$save$'
        Open chatlog.txt file
        Write SaveBuffer to file
        Print save message to Terminal
        Close file
    Else
        Include Username to message
        Send message to server socket

```

### ReadThread

```

Loop forever
    If there is buffer from socket
        Receive buffer
    Append buffer to SaveBuffer
    Print buffer to Terminal

```

## Running Server

### Server

```
Create socket
Fill socket structure with IP address and Port number
Bind socket structure to socket
Listen for connections
Initialize client list
Loop forever
    Select active socket
    Loop through client list
        If slot is empty
            Set active socket to slot
    Loop through active sockets
        If socket has data
            Accept socket
            Read buffer from socket
            Print buffer to Terminal
            Write buffer to all active sockets
```

## Test Cases
